ABSTRACT

Left-handers are reputed to be shorter than right-handers. However, previous research has confounded handedness direction (left- versus right-handedness) with handedness strength (consistency with which one hand is chosen across a variety of tasks; consistent- versus inconsistent-handedness). Here, we support a relationship between handedness strength, but not direction, and stature, with increasing inconsistent-handedness associated with increasing self-reported height.

Keywords: Handedness; Stature; Prenatal Testosterone

1. Introduction

Left-handers are reputed to be shorter than right-handers [1-4]. However, previous work has assessed handedness via archival records of sports figures, using one activity (e.g. batting) to classify handedness, thereby confounding handedness direction (left- versus right-handedness) with handedness strength (consistency with which one hand is chosen across a variety of tasks; consistent- versus inconsistent-handedness). Handedness direction and strength both contribute to between-subject variation in cognitive/physiological measures [5], and are likely to contribute to individual differences in handedness effects on stature as well, presumably via prenatal androgen exposure variation. In the only study [6] directly querying participants' handedness, increasing consistent-left and consistent-right-handedness were both associated with decreased height. However, in that study, handedness was dichotomized, which does not allow for assessment of overall direction versus strength of handedness and height relationships. Furthermore, it is unclear how height was assessed. Here, in this Short Report, we support a relationship between handedness strength, but not direction, and stature.

2. Methods

As part of a larger protocol, participants (N = 141) com-

pleted written consent (the study was approved via the MSU Institutional Review Board and the Army Human Research Protection Office), self-reported their height, and filled out the Edinburgh Handedness Inventory (EHI). The EHI consists of 10 activities that participants rate as performing with the right or left hand "always", "usually", or having no hand preference. Graded scoring results in a range from -100 (perfectly consistent-left-handedness) to +100 (perfectly consistent-right-handedness).

3. Results

Handedness Direction: Unpaired t-test comparing height (cm) between left- (n = 12; EHI score equal/below 0) and right- (n = 129; EHI score above 0) handers was non-significant (p > 0.20). Height also did not correlate with EHI overall or as a function of gender (p > 0.30). See **Figure 1(a)**.

Handedness Strength: Height negatively correlated with absolute value of EHI (|EHI|), $r(139) = -0.22$, $p < 0.01$, a measure that collapses across handedness direction, while maintaining handedness strength. See **Figure 1(b)**. This effect was evident in men (n = 35, $r = -0.41$, $p = 0.01$), but not women (n = 106; $p > 0.90$).

Handedness Direction and Strength: Handedness was trichotomized into consistent-left-(CLH), right-(CRH), and inconsistent-handed (ICH) groups via the median of the |EHI| score (|80|) [see 5]. Scores +80 and above were

*Corresponding author.

CRH (n = 71), scores -80 and below were CLH (n = 7), and scores +75 to -75 were ICH (n = 63); A one-way Analysis of Variance revealed an effect ($f(2,138) = 3.0, p = 0.05$); ICH ($x = 168.41, sd = 11.47$) were taller (by 3.72 cm) than CRH ($x = 164.69, sd = 8.66$; Fisher's PLSD, $p < 0.05$), and marginally (Fisher's PLSD $p = 0.10$) taller (by 6.58 cm) than CLH ($x = 161.83, sd = 9.92$). See **Figure 2**.

4. Discussion

Handedness strength (measured via the absolute value of

shared mediation by in utero hormonal factors (e.g. testosterone), a suggestion supported by the fact that men, not women, demonstrated this relationship. Left- and right-handers did not differ from each other, nor did consistent-right- and consistent-left-handers. Inconsistent-handers however were taller than both consistently-handed groups, and significantly so relative to consistent-right-handers. Limitations of the present finding are based primarily on the limited number of participants, the need for additional testing of men and women, and the reliance on self-reported height. Nevertheless, the results call into question previously analyzed archival data based on single measures of handedness. The results here further support that non-right-handedness is not a homogeneous trait that can be determined by performance on one activity [5]. Given that inconsistent-handers are taller than both consistent-left- and consistent-right-handers, data sets that incorporate strength of hand preference may more accurately characterize the relationship between height and hand preference.
